Functional un unparsing

Kenichi Asai (Ochanomizu) Oleg Kiselyov (FNMOC) Chung-chieh Shan (Rutgers)

```
printf("%d-th character after %c is %c", 5, 'a', 'f');
(
5-th character after a is f
(
scanf("%d-th character after %c is %c", &i, &c1, &c2);
```

Number and types of arguments depend on format descriptor. Do we need dependent types?

Danvy (1998): printf in mere Hindley-Milner. Today: derive printf and scanf.

```
printf("%d-th character after %c is %c", 5, 'a', 'f');
(
5-th character after a is f
(
scanf("%d-th character after %c is %c", &i, &c1, &c2);
```

Number and types of arguments depend on format descriptor. Do we need dependent types?

Danvy (1998): printf in mere Hindley-Milner. Today: derive printf and scanf.

```
printf("%d-th character after %c is %c", 5, 'a', 'f');
(
5-th character after a is f

specification
implementation

printf

scanf

What is a spec?

"A specification is a set of sentences in some logical language. The names of the functions, predicates, and procedures which the specification is intended to specify appear as nonlogical symbols in these sentences."

> --- "Specifications, models, and implementations of data abstractions" (Wand 1982)

Our nonlogical symbols: printf, scanf, sequence constructors.

What is a spec?

"A specification is a set of sentences in some logical language. The names of the functions, predicates, and procedures which the specification is intended to specify appear as nonlogical symbols in these sentences."

> ---"Specifications, models, and implementations of data abstractions" (Wand 1982)

Our nonlogical symbols: printf, scanf, sequence constructors.

```
"%d-th character after %c is %c"
```

consD int (consD (lit " -th character after ")
 (consD char (consD (lit " is ") (consD char nilD))))

```
[int; lit "-th character after ";
char; lit " is "; char]<sub>D</sub>
```

```
printf nilD nilA = nilS
printf (consD (lit str) ds) (consA () xs)
= consS str (printf ds xs)
printf (consD char ds) (consA c xs)
= consS (string_of_char c) (printf ds xs)
printf (consD int ds) (consA i xs)
= consS (string_of_int i) (printf ds xs)
```

```
printf nilD nilA = nilS
printf (consD (lit str) ds) (consA () xs)
= consS str (printf ds xs)
printf (consD char ds) (consA c xs)
= consS (string_of_char c) (printf ds xs)
printf (consD int ds) (consA i xs)
= consS (string_of_int i) (printf ds xs)
```

```
printf nilD nilA = nilS
printf (consD d ds) (consA x xs)
= consS (d x) (printf ds xs)
```

lit str () = str char c = string_of_char c int i = string_of_int i

ESSENTIALS OF PROGRAMMING LANGUAGES

THIRD EDITION

Daniel P. Friedman and Mitchell Wand

The Interpreter Recipe

- 1. Look at a piece of data.
- 2. Decide what kind of data it represents.
- 3. Extract the components of the datum and do the right thing with them.

```
scanf [int; lit "-th character after ";
    char; lit " is "; char]<sub>D</sub>
    "5-th character after a is f"
= fun f -> f 5 'a' 'f'
```

```
scanf nilD nilS = nilA
scanf (consD (lit str) ds) (consS s ss)
= consA (assert (str = s)) (scanf ds ss)
scanf (consD char ds) (consS s ss)
= consA (char_of_string s) (scanf ds ss)
scanf (consD int ds) (consS s ss)
= consA (int_of_string s) (scanf ds ss)
```

```
scanf nilD nilS = nilA
scanf (consD (lit str) ds) (consS s ss)
= consA (assert (str = s)) (scanf ds ss)
scanf (consD char ds) (consS s ss)
= consA (char_of_string s) (scanf ds ss)
scanf (consD int ds) (consS s ss)
= consA (int_of_string s) (scanf ds ss)
```

```
scanf nilD nilS = nilA
scanf (consD d ds) (consS s ss)
= consS (d s) (scanf ds ss)
```

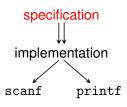

lit str s = assert (str = s)
char s = char_of_string s
int s = int_of_string s

Specification of printf and scanf

```
printf nilD nilA = nilS
printf (consD d ds) (consA x xs)
= consS (d x) (printf ds xs)
```

```
scanf nilD nilS = nilA
scanf (consD d ds) (consS s ss)
= consS (d s) (scanf ds ss)
```

Both just zipWith id!

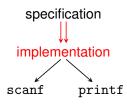

On to implementation

Recurring idea: fuse format descriptors with their contexts of use.

(inline; specialize)

"By considering continuations, local transformation strategies can take advantage of global knowledge."

> ----Continuation-based program transformation strategies" (Wand 1980)

Both printf and scanf are just zipWith id.

```
printf nilD nilA = nilS
printf (consD d ds) (consA x xs)
= consS (d x) (printf ds xs)
```

Both printf and scanf are just zipWith id.

```
printf nilD nilA = nilS
printf (consD d ds) (consA x xs)
= consS (d x) (printf ds xs)
```

It's a compositional interpreter-matching definition of a fold:

```
fold z g nil = z
fold z g (cons x xs) = g x (fold z g xs)
Hence, printf is a fold:
printf = fold z g where
z nilA = nilS
g d ds (consA x xs) = consS (d x) (ds xs)
```

Both printf and scanf are just zipWith id.

```
printf nilD nilA = nilS
printf (consD d ds) (consA x xs)
= consS (d x) (printf ds xs)
```

It's a compositional interpreter-matching definition of a fold:

fold z g nil = z fold z g (cons x xs) = g x (fold z g xs)

Hence, printf is a fold, and the descriptor can be deforested:

```
printf = id
nilD nilA = nilS
consD d ds (consA x xs) = consS (d x) (ds xs)
```

Both printf and scanf are just zipWith id.

```
printf nilD nilA = nilS
printf (consD d ds) (consA x xs)
= consS (d x) (printf ds xs)
```

It's a compositional interpreter-matching definition of a fold:

fold z g nil = z
fold z g (cons x xs) = g x (fold z g xs)

Hence, printf is a fold, and the descriptor can be deforested:

```
printf = id
nilD () = ()
consD d ds (x, xs) = (d x, ds xs)
```

Choose tuple representation.

Both printf and scanf are just zipWith id.

```
printf nilD nilA = nilS
printf (consD d ds) (consA x xs)
= consS (d x) (printf ds xs)
```

It's a compositional interpreter-matching definition of a fold:

fold z g nil = z fold z g (cons x xs) = g x (fold z g xs)

Hence, printf is a fold, and the descriptor can be deforested:

```
printf = id scanf = id
nilD () = ()
consD d ds (x, xs) = (d x, ds xs)
```

Choose tuple representation. Same with scanf.

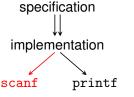

Not quite the standard scanf

We have:

We want:

```
scanf [int; lit "-th character after "; char; lit " is ";
    "5-th character after a is f"
= fun f -> f 5 'a' 'f'
```

Fix: fuse primitive descriptors with consD.

nilD () = nilA consD d ds (s,ss) = consA (d s) (ds ss)

Fuse each primitive descriptor with consD.

lit str s = assert (str = s)
char s = char_of_string s
int s = int_of_string s

nilD () = nilA consD d = d

Fuse each primitive descriptor with consD.

lit str	ds	(s,ss)	=	consA	(assert (str = s))	(ds	ss)
char	ds	(s,ss)	=	consA	<pre>(char_of_string s)</pre>	(ds	ss)
int	ds	(s,ss)	=	consA	(int_of_string s)	(ds	ss)

Primitive descriptors can consume and produce different amounts.

nilD () = nilA consD d = d

Fuse each primitive descriptor with consD.

lit str	ds	(s,ss) =	consA	(assert (str = s))	(ds ss)
char	ds	(s,ss) =	consA	(char_of_string s)	(ds ss)
int	ds	(s,ss) =	consA	(int_of_string s)	(ds ss)

Primitive descriptors can consume and produce different amounts.

```
char ds inp
= if String.length inp > 0
then consA (inp.[0])
        (ds (String.sub inp 1 (String.length inp - 1)))
else failwith "scanf char"
```

nilD () = nilA consD d = d

Fuse each primitive descriptor with consD.

lit str	ds	(s,ss) =	consA	(assert (str = s))	(ds ss)
char	ds	(s,ss) =	consA	(char_of_string s)	(ds ss)
int	ds	(s,ss) =	consA	<pre>(int_of_string s)</pre>	(ds ss)

Primitive descriptors can consume and produce different amounts.

```
char <mark>ds</mark> inp
```

(ds (String.sub inp 1 (String.length inp - 1)))
else failwith "scanf char"

nilD () = nilA consD d = d

Fuse each primitive descriptor with consD.

lit str	ds	(s,ss) =	consA	(assert (str = s))	(ds ss)
char	ds	(s,ss) =	consA	(char_of_string s)	(ds ss)
int	ds	(s,ss) =	consA	<pre>(int_of_string s)</pre>	(ds ss)

Primitive descriptors can consume and produce different amounts.

```
lit str ds inp
= if String.length str <= String.length inp &&
    str = String.sub inp 0 (String.length str)
    then ds (String.sub inp (String.length str)
        (String.length inp - String.length str))
    else failwith "scanf lit"</pre>
```

nilD () = nilA consD d = d

Fuse each primitive descriptor with consD.

lit str	ds	(s,ss) =	consA	(assert (str = s))	(ds ss)
char	ds	(s,ss) =	consA	(char_of_string s)	(ds ss)
int	ds	(s,ss) =	consA	<pre>(int_of_string s)</pre>	(ds ss)

Primitive descriptors can consume and produce different amounts.

```
lit str ds inp
= if String.length str <= String.length inp &&
    str = String.sub inp 0 (String.length str)
    then ds (String.sub inp (String.length str)
        (String.length inp - String.length str))
    else failwith "scanf lit"</pre>
```

nilD "" = nilA consD d = d

Fuse each primitive descriptor with consD.

lit str	ds	(s,ss)	=	consA	(assert (str = s))	(ds	ss)
char	ds	(s,ss)	=	consA	(char_of_string s)	(ds	ss)
int	ds	(s,ss)	=	consA	<pre>(int_of_string s)</pre>	(ds	ss)

Primitive descriptors can consume and produce different amounts. Finally, Church-encode parsing results.

let nilA = fun f -> f

let consA x xs = fun f \rightarrow xs (f x)

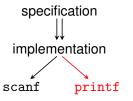

Done!

Not quite the standard printf

We have:

```
printf [int; lit "-th character after "; char; lit " is ";
5 'a' 'f'
= "5-th character after a is f"
```

Fix: fuse *descriptors* with consD (i.e., transform them to CPS).

Begin by symmetry with scanf:

printf ds = ds nilD = "" consD d = d

Input: nested tuple without (). Output: single string.

Begin by symmetry with scanf:

printf ds = ds nilD = "" consD d = d

Input: nested tuple without (). Output: single string.

If only we had = (.....) xs then we could just curry and eta-reduce.

Begin by symmetry with scanf:

printf ds = ds id nilD k = k "" consD d = d

Input: nested tuple without (). Output: single string.

Pass continuation to ds.

Begin by symmetry with scanf:

printf ds = ds id nilD k = k "" consD d = d

Input: nested tuple without (). Output: single string.

lit str	ds	(xs)	=	str	^	ds	xs
char	ds	(c,xs)	=	<pre>string_of_char c</pre>	^	ds	xs
int	ds	(i,xs)	=	string_of_int i	^	ds	xs

Pass continuation to ds, then curry and eta-reduce.

Begin by symmetry with scanf:

printf ds = ds id nilD k = k "" consD d = d

Input: nested tuple without (). Output: single string.

lit str	ds	(xs)	=	str	^	ds	xs
char	ds	(c,xs)	=	<pre>string_of_char c</pre>	^	ds	xs
int	ds	(i,xs)	=	string_of_int i	^	ds	xs

Pass continuation to ds, then curry and eta-reduce. Done!

Representing control

Continuation-passing style:

printf ds = ds id consD d = d nilD k = k ""
lit str ds k = ds (fun s -> k (str ^ s))
char ds k c = ds (fun s -> k (string_of_char c ^ s))
int ds k i = ds (fun s -> k (string_of_int i ^ s))

A chain of closures builds up.

"The solution is a more abstract view of the domain of continuations. What we need is an abstract algebra for modeling the rest of a computation and its operations."

> —"Abstract continuations" (Felleisen, Wand, Friedman & Duba 1988)

Representing control

Continuation-passing style:

printf ds = ds id consD d = d nilD k = k ""
lit str ds k = ds (fun s -> k (str ^ s))
char ds k c = ds (fun s -> k (string_of_char c ^ s))
int ds k i = ds (fun s -> k (string_of_int i ^ s))

"Data-structure continuations":

printf ds = ds "" consD d = d nilD k = k
lit str ds k = ds (k ^ str)
char ds k c = ds (k ^ string_of_char c)
int ds k i = ds (k ^ string_of_int i)

See paper for direct style: consD becomes just ^ A new solution: reset (fun () -> printf [...]_D 5 'a' 'f')

"Though this be madness, yet there is method in 't." —*Hamlet* (Shakespeare)

Principles established by Mitch are now clichés. We use them to derive printf and scanf.

Thanks! To more decades to come.
